Table of Contents

About.....	1
Chapter 1: Getting started with jQuery.....	2
Remarks.....	2
Versions.....	2
Examples.....	3
jQuery Namespace ("jQuery" and "\$").....	3
Getting Started.....	3
Explanation of code.....	4
Include script tag in head of HTML page.....	5
Avoiding namespace collisions.....	6
Loading jQuery via console on a page that does not have it.....	8
The jQuery Object.....	8
Loading namespaced jQuery plugins.....	8
Chapter 2: Ajax.....	10
Syntax.....	10
Parameters.....	10
Remarks.....	10
Examples.....	10
Handling HTTP Response Codes with \$.ajax().....	11
Using Ajax to Submit a Form.....	11
Sending JSON data.....	12
All in one examples.....	13
Ajax Abort a Call or Request.....	14
Ajax File Uploads.....	15
1. A Simple Complete Example.....	15
2. Working With File Inputs.....	15
3. Creating and Filling the FormData.....	16
4. Sending the Files With Ajax.....	16
Chapter 3: Append.....	18
Syntax.....	18

Parameters.....	18
Remarks.....	18
Examples.....	18
Appending an element to a container.....	18
Efficient consecutive .append() usage.....	19
HTML.....	19
JS.....	19
DO NOT do this.....	20
Add to a separate array, append after loop completes.....	20
Using modern Array.* methods.....	21
Using strings of HTML (instead of jQuery built-in methods).....	21
Manually create elements, append to document fragment.....	22
Dive deeper.....	22
jQuery append.....	23
Chapter 4: Attributes.....	24
Remarks.....	24
Examples.....	24
Get the attribute value of a HTML element.....	24
Setting value of HTML attribute.....	25
Removing attribute.....	25
Differece between attr() and prop().....	25
Chapter 5: Checkbox Select all with automatic check/uncheck on other checkbox change.....	26
Introduction.....	26
Examples.....	26
2 select all checkboxes with corresponding group checkboxes.....	26
Chapter 6: CSS Manipulation.....	27
Syntax.....	27
Remarks.....	27
Examples.....	28
Set CSS property.....	28
Get CSS property.....	28

Increment/Decrement Numeric Properties.....	28
CSS – Getters and Setters.....	28
CSS Getter.....	29
CSS Setter.....	29
Chapter 7: document-ready event.....	30
Examples.....	30
What is document-ready and how should I use it?.....	30
jQuery 2.2.3 and earlier.....	31
jQuery 3.0.....	31
Notation.....	31
Asynchronous.....	31
Difference between \$(document).ready() and \$(window).load().....	32
Attaching events and manipulating the DOM inside ready().....	32
Difference between jQuery(fn) and executing your code before.....	33
Chapter 8: DOM Manipulation.....	34
Examples.....	34
Creating DOM elements.....	34
Manipulating element classes.....	34
Other API Methods.....	37
.html().....	38
Sorting elements.....	38
Make it cute.....	39
Add a sort button.....	39
Set the initial value of sorting direction.....	40
Cache our DOM elements and sortList() out here to minimize our DOM processing.....	40
Wrap everything up in a doSort() function.....	40
Add click handler for \$('#btn-sort').....	40
All together now.....	40
Multi-level sorting (grouping sorted elements).....	41
Add another button to toggle disabled group sorting.....	42
Chapter 9: DOM Traversing.....	43
Examples.....	43

Select children of element	43
Iterating over list of jQuery elements	43
Selecting siblings	44
closest() method	44
Get next element	45
Get previous element	46
Filter a selection	46
The HTML	46
Selector	46
Function	47
Elements	47
Selection	47
find() method	47
Chapter 10: Each function	49
Examples	49
Basic use	49
jQuery each function	49
Chapter 11: Element Visibility	50
Parameters	50
Examples	50
Overview	50
Toggle possibilities	50
Chapter 12: Events	53
Remarks	53
Examples	53
Attach and Detach Event Handlers	53
Attach an Event Handler	53
HTML	53
jQuery	53
Detach an Event Handler	53
HTML	53
jQuery	53

jQuery.....	54
Delegated Events.....	54
Example HTML.....	54
The problem.....	54
Background information - Event propagation.....	55
Solution.....	55
In detail how solution works.....	55
Document Loading Event .load().....	56
Events for repeating elements without using ID's.....	56
originalEvent.....	57
Get Scroll Direction.....	57
Switching specific events on and off via jQuery. (Named Listeners).....	58
Chapter 13: Getting and setting width and height of an element.....	59
Examples.....	59
Getting and setting width and height (ignoring border).....	59
Getting and setting innerWidth and innerHeight (ignoring padding and border).....	59
Getting and setting outerWidth and outerHeight (including padding and border).....	59
Chapter 14: jQuery .animate() Method.....	61
Syntax.....	61
Parameters.....	61
Examples.....	61
Animation with callback.....	61
Chapter 15: jQuery Deferred objects and Promises.....	64
Introduction.....	64
Examples.....	64
Basic promise creation.....	64
Asynchronous Promises Chaining.....	64
jQuery ajax() success, error VS .done(), .fail().....	65
Get the current state of a promise.....	66
Chapter 16: Plugins.....	67
Examples.....	67

Plugins - Getting Started	67
jQuery.fn.extend() method	69
Chapter 17: Prepend	70
Examples	70
Prepending an element to a container	70
Prepend method	70
Chapter 18: Selectors	72
Introduction	72
Syntax	72
Remarks	72
Examples	72
Types of Selectors	72
Combining selectors	75
Descendant and child selectors	76
Other combinators	76
Group Selector : ","	76
Multiples selector : "" (no character)	76
Adjacent Sibling Selector : "+"	77
General Sibling Selector : "~"	77
Overview	77
Basic selectors	77
Relational operators	77
Caching Selectors	77
DOM Elements as selectors	78
HTML strings as selectors	79
Credits	80

About

You can share this PDF with anyone you feel could benefit from it, downloaded the latest version from: [jquery](#)

It is an unofficial and free jQuery ebook created for educational purposes. All the content is extracted from [Stack Overflow Documentation](#), which is written by many hardworking individuals at Stack Overflow. It is neither affiliated with Stack Overflow nor official jQuery.

The content is released under Creative Commons BY-SA, and the list of contributors to each chapter are provided in the credits section at the end of this book. Chapter 1: Getting started with jQuery

Remarks

jQuery is a JavaScript library which simplifies DOM operations, event handling, AJAX, and animations. It also takes care of many browser compatibility issues in underlying DOM and javascript engines.

Each version of jQuery can be downloaded from <https://code.jquery.com/jquery/> in both compressed (minified) and uncompressed formats.

Versions

Version	Notes	Release Date
1.0	First stable release	2006-08-26
1.1		2007-01-14
1.2		2007-09-10
1.3	Sizzle introduced into core	2009-01-14
1.4		2010-01-14
1.5	Deferred callback management, ajax module rewrite	2011-01-31
1.6	Significant performance gains in the <code>attr()</code> and <code>val()</code> methods	2011-05-03
1.7	New Event APIs: <code>on()</code> and <code>off()</code> .	2011-11-03
1.8	Sizzle rewritten, improved animations and <code>\$(html, props)</code> flexibility.	2012-08-09
1.9	Removal of deprecated interfaces and code cleanup	2013-01-15
1.10	Incorporated bug fixes and differences reported from both the 1.9 and 2.0 beta cycles	2013-05-24
1.11		2014-01-24
1.12		2016-01-08
2.0	Dropped IE 6–8 support for performance improvements and reduction in size	2013-04-18
2.1		2014-01-24

Version	Notes	Release Date
2.2		2016-01-08
3.0	Massive speedups for some jQuery custom selectors	2016-06-09
3.1	No More Silent Errors	2016-07-07

Examples

jQuery Namespace ("jQuery" and "\$")

jQuery is the starting point for writing any jQuery code. It can be used as a function `jQuery(...)` or a variable `jQuery.foo`.

\$ is an alias for jQuery and the two can usually be interchanged for each other (except where `jQuery.noConflict();` has been used - see [Avoiding namespace collisions](#)).

Assuming we have this snippet of HTML -

```
<div id="demo_div" class="demo"></div>
```

We might want to use jQuery to add some text content to this div. To do this we could use the jQuery `text()` function. This could be written using either `jQuery` or `$`. i.e. -

```
jQuery("#demo_div").text("Demo Text!");
```

Or -

```
$("#demo_div").text("Demo Text!");
```

Both will result in the same final HTML -

```
<div id="demo_div" class="demo">Demo Text!</div>
```

As \$ is more concise than jQuery it is the generally the preferred method of writing jQuery code.

jQuery uses CSS selectors and in the example above an ID selector was used. For more information on selectors in jQuery see [types of selectors](#).

Getting Started

Create a file `hello.html` with the following content:

```
<!DOCTYPE html>
<html>
<head>
```

```

<title>Hello, World!</title>
</head>
<body>
  <div>
    <p id="hello">Some random text</p>
  </div>
  <script src="https://code.jquery.com/jquery-2.2.4.min.js"></script>
  <script>
    $(document).ready(function() {
      $('#hello').text('Hello, World!');
    });
  </script>
</body>
</html>

```

[Live Demo on JSBin](#)

Open this file in a web browser. As a result you will see a page with the text: Hello, World!

Explanation of code

1. Loads the jQuery library from the jQuery [CDN](#):

```
<script src="https://code.jquery.com/jquery-2.2.4.min.js"></script>
```

This introduces the `$` global variable, an alias for the `jQuery` function and namespace.

*Be aware that one of the most common mistakes made when including jQuery is failing to load the library **BEFORE** any other scripts or libraries that may depend on or make use of it.*

2. Defers a function to be executed when the DOM ([Document Object Model](#)) is detected to be "ready" by jQuery:

```

// When the `document` is `ready`, execute this function `...`
$(document).ready(function() { ... });

// A commonly used shorthand version (behaves the same as the above)
$(function() { ... });

```

3. Once the DOM is ready, jQuery executes the callback function shown above. Inside of our function, there is only one call which does 2 main things:

1. Gets the element with the `id` attribute equal to `hello` (our [selector](#) `#hello`). Using a selector as the passed argument is the core of jQuery's functionality and naming; the entire library essentially evolved from extending [document.querySelector](#)^{MDN}.
2. Set the `text()` inside the selected element to `Hello, World!`.

```

#      ↓ - Pass a `selector` to `$` jQuery, returns our element
$('#hello').text('Hello, World!');
#      ↑ - Set the Text on the element

```

For more refer to the [jQuery - Documentation](#) page.

Include script tag in head of HTML page

To load **jQuery** from the official [CDN](#), go to the jQuery [website](#). You'll see a list of different versions and formats available.

jQuery CDN – Latest Stable Version

Powered by [MaxCDN](#)

jQuery Core

Showing the latest stable release in each major branch. [See all versions of jQuery Core.](#)

jQuery 3.x

- jQuery Core 3.1.0 - [uncompressed](#), [minified](#), [slim](#), [slim minified](#)

jQuery 2.x

- jQuery Core 2.2.4 - [uncompressed](#), [minified](#)

jQuery 1.x

- jQuery Core 1.12.4 - [uncompressed](#), [minified](#)

Now, copy the source of the version of jQuery, you want to load. Suppose, you want to load **jQuery 2.X**, click **uncompressed** or **minified** tag which will show you something like this:

jQuery CDN - Latest Stable Version

Powered by **MaxCDN**

Code Integration

```
<script
  src="https://code.jquery.com/jquery-2.2.4.min.js"
  integrity="sha256-bbntvQ1/R47Rjagbdqdslwq8LackIXxZKRut1T44="
  crossorigin="anonymous"></script>
```

The `integrity` and `crossorigin` attributes are used for [Subresource Integrity \(SRI\) checking](#). This ensure that resources hosted on third-party servers have not been tampered with. Use of SRI is recommended practice, whenever libraries are loaded from a third-party source. Read more at srihash.org

- jQuery Core 2.2.4 - [uncompressed](#), [minified](#)

jQuery 1.x

- jQuery Core 1.12.4 - [uncompressed](#), [minified](#)

Copy the full code (or click on the copy icon) and paste it in the `<head>` or `<body>` of your html.

The best practice is to load any external JavaScript libraries at the head tag with the `async` attribute. Here is a demonstration:

```
<!DOCTYPE html>
<html>
  <head>
    <title>Loading jquery-2.2.4</title>
    <script src="https://code.jquery.com/jquery-2.2.4.min.js" async></script>
  </head>
  <body>
    <p>This page is loaded with jquery.</p>
  </body>
</html>
```

When using `async` attribute be conscious as the javascript libraries are then asynchronously loaded and executed as soon as available. If two libraries are included where second library is dependent on the first library is this case if second library is loaded and executed before first library then it may throw an error and application may break.

Avoiding namespace collisions

Libraries other than jQuery may also use `$` as an alias. This can cause interference between those libraries and jQuery.

To release `$` for use with other libraries:

```
jQuery.noConflict();
```

After calling this function, `$` is no longer an alias for `jQuery`. However, you can still use the variable `jQuery` itself to access jQuery functions:

```
jQuery('#hello').text('Hello, World!');
```

Optionally, you can assign a different variable as an alias for jQuery:

```
var jqy = jQuery.noConflict();  
jqy('#hello').text('Hello, World!');
```

Conversely, to prevent other libraries from interfering with jQuery, you can wrap your jQuery code in an **immediately invoked function expression (IIFE)** and pass in `jQuery` as the argument:

```
(function($) {  
    $(document).ready(function() {  
        $('#hello').text('Hello, World!');  
    });  
})(jQuery);
```

Inside this IIFE, `$` is an alias for jQuery only.

Another simple way to **secure jQuery's \$ alias and make sure DOM is ready**:

```
jQuery(function( $ ) { // DOM is ready  
    // You're now free to use $ alias  
    $('#hello').text('Hello, World!');  
});
```

To summarize,

- `jQuery.noConflict()` : `$` no longer refers to jQuery, while the variable `jQuery` does.
- `var jQuery2 = jQuery.noConflict()` - `$` no longer refers to jQuery, while the variable `jQuery` does and so does the variable `jQuery2`.

Now, there exists a third scenario - What if we want jQuery to be available **only in jQuery2**? Use,

```
var jQuery2 = jQuery.noConflict(true)
```

This results in neither `$` nor `jQuery` referring to jQuery.

This is useful when multiple versions of jQuery are to be loaded onto the same page.

```
<script src='https://code.jquery.com/jquery-1.12.4.min.js'></script>  
<script>  
    var jQuery1 = jQuery.noConflict(true);  
</script>  
<script src='https://code.jquery.com/jquery-3.1.0.min.js'></script>  
<script>  
    // Here, jQuery1 refers to jQuery 1.12.4 while, $ and jQuery refers to jQuery 3.1.0.  
</script>
```

Loading jQuery via console on a page that does not have it.

Sometimes one has to work with pages that are not using jQuery while most developers are used to have jQuery handy.

In such situations one can use Chrome Developer Tools console (F12) to manually add jQuery on a loaded page by running following:

```
var j = document.createElement('script');
j.onload = function(){ jQuery.noConflict(); };
j.src = "https://ajax.googleapis.com/ajax/libs/jquery/1.12.4/jquery.min.js";
document.getElementsByTagName('head')[0].appendChild(j);
```

Version you want might differ from above(1.12.4) you can get the link for [one you need here](#).

The jQuery Object

Every time jQuery is called, by using `$()` or `jQuery()`, internally it is creating a new instance of jQuery. This is the [source code](#) which shows the new instance:

```
// Define a local copy of jQuery
jQuery = function( selector, context ) {

    // The jQuery object is actually just the init constructor 'enhanced'
    // Need init if jQuery is called (just allow error to be thrown if not included)
    return new jQuery.fn.init( selector, context );
}
```

Internally jQuery refers to its prototype as `.fn`, and the style used here of internally instantiating a jQuery object allows for that prototype to be exposed without the explicit use of `new` by the caller.

In addition to setting up an instance (which is how the jQuery API, such as `.each`, `children`, `filter`, etc. is exposed), internally jQuery will also create an array-like structure to match the result of the selector (provided that something other than nothing, `undefined`, `null`, or similar was passed as the argument). In the case of a single item, this array-like structure will hold only that item.

A simple demonstration would be to find an element with an id, and then access the jQuery object to return the underlying DOM element (this will also work when multiple elements are matched or present).

```
var $div = $("#myDiv");//populate the jQuery object with the result of the id selector
var div = $div[0];//access array-like structure of jQuery object to get the DOM Element
```

Loading namespaced jQuery plugins

Typically when loading plugins, make sure to always include the plugin *after* jQuery.

```
<script src="https://code.jquery.com/jquery-3.1.1.min.js"></script>
<script src="some-plugin.min.js"></script>
```

If you *must* use more than one version of jQuery, then make sure to load the plugin(s) *after* the required version of jQuery followed by code to set `jQuery.noConflict(true)`; then load the next version of jQuery and its associated plugin(s):

```
<script src="https://code.jquery.com/jquery-1.7.0.min.js"></script>
<script src="plugin-needs-1.7.min.js"></script>
<script>
// save reference to jQuery v1.7.0
var $oldjq = jQuery.noConflict(true);
</script>
<script src="https://code.jquery.com/jquery-3.1.1.min.js"></script>
<script src="newer-plugin.min.js"></script>
```

Now when initializing the plugins, you'll need to use the associated jQuery version

```
<script>
// newer jQuery document ready
jQuery(function($){
  // "$" refers to the newer version of jQuery
  // inside of this function

  // initialize newer plugin
  $('#new').newerPlugin();
});

// older jQuery document ready
$oldjq(function($){
  // "$" refers to the older version of jQuery
  // inside of this function

  // initialize plugin needing older jQuery
  $('#old').olderPlugin();
});
</script>
```

It is possible to only use one document ready function to initialize both plugins, but to avoid confusion and problems with any extra jQuery code inside the document ready function, it would be better to keep the references separate.

Read *Getting started with jQuery* online: <https://riptutorial.com/jquery/topic/211/getting-started-with-jquery>

Chapter 2: Ajax

Syntax

- `var jqXHR = $.ajax( url [,settings] )`
- `var jqXHR = $.ajax( [settings] )`
- `jqXHR.done(function( data, textStatus, jqXHR ) {});`
- `jqXHR.fail(function( jqXHR, textStatus, errorThrown ) {});`
- `jqXHR.always(function( jqXHR ) {});`

Parameters

Parameter	Details
url	Specifies the URL to which the request will be sent
settings	an object containing numerous values that affect the behavior of the request
type	The HTTP method to be used for the request
data	Data to be sent by the request
success	A callback function to be called if the request succeeds
error	A callback to handle error
statusCode	An object of numeric HTTP codes and functions to be called when the response has the corresponding code
dataType	The type of data that you're expecting back from the server
contentType	Content type of the data to sent to the server. Default is "application/x-www-form-urlencoded; charset=UTF-8"
context	Specifies the context to be used inside callbacks, usually <code>this</code> which refers to the current target.

Remarks

AJAX stands for **A**synchronous **J**avaScript **a**nd **X**ML. AJAX allows a webpage to perform an asynchronous HTTP (AJAX) request to the server and receive a response, without needing to reload the entire page.

Examples

Handling HTTP Response Codes with \$.ajax()

In addition to `.done`, `.fail` and `.always` promise callbacks, which are triggered based on whether the request was successful or not, there is the option to trigger a function when a specific [HTTP Status Code](#) is returned from the server. This can be done using the `statusCode` parameter.

```
$.ajax({
  type: {POST or GET or PUT etc.},
  url: {server.url},
  data: {someData: true},
  statusCode: {
    404: function(responseObject, textStatus, jqXHR) {
      // No content found (404)
      // This code will be executed if the server returns a 404 response
    },
    503: function(responseObject, textStatus, errorThrown) {
      // Service Unavailable (503)
      // This code will be executed if the server returns a 503 response
    }
  }
})
.done(function(data) {
  alert(data);
})
.fail(function(jqXHR, textStatus) {
  alert('Something went wrong: ' + textStatus);
})
.always(function(jqXHR, textStatus) {
  alert('Ajax request was finished')
});
```

As official jQuery documentation states:

If the request is successful, the status code functions take the same parameters as the success callback; if it results in an error (including 3xx redirect), they take the same parameters as the `error` callback.

Using Ajax to Submit a Form

Sometimes you may have a form and want to submit it using ajax.

Suppose you have this simple form -

```
<form id="ajax_form" action="form_action.php">
  <label for="name">Name :</label>
  <input name="name" id="name" type="text" />
  <label for="email">Email :</label>
  <input name="email" id="email" type="text" />
  <input type="submit" value="Submit" />
</form>
```

The following jQuery code can be used (within a `$(document).ready` call) -

```
$('#ajax_form').submit(function(event) {
```

```

event.preventDefault();
var $form = $(this);

$.ajax({
  type: 'POST',
  url: $form.attr('action'),
  data: $form.serialize(),
  success: function(data) {
    // Do something with the response
  },
  error: function(error) {
    // Do something with the error
  }
});
});

```

Explanation

- `var $form = $(this)` - the form, cached for reuse
- `$('#ajax_form').submit(function(event) {` - When the form with ID "ajax_form" is submitted run this function and pass the event as a parameter.
- `event.preventDefault();` - Prevent the form from submitting normally (Alternatively we can use `return false` after the `ajax({});` statement, which will have the same effect)
- `url: $form.attr('action'),` - Get the value of the form's "action" attribute and use it for the "url" property.
- `data: $form.serialize(),` - Converts the inputs within the form into a string suitable for sending to the server. In this case it will return something like `"name=Bob&email=bob@bobsemailaddress.com"`

Sending JSON data

jQuery makes handling *JSON responses* painless, but a bit more work is required when a given request wishes you to *send* data in JSON format:

```

$.ajax("/json-consuming-route", {
  data: JSON.stringify({author: {name: "Bullwinkle J. Moose",
                                email: "bullwinkle@example.com"} }),
  method: "POST",
  contentType: "application/json"
});

```

Observe that we're specifying **the correct `contentType`** for the data we're sending; this is a good practice in general and may be required by the API you're posting to - but it *also* has the side-effect of instructing jQuery not to perform the default conversion of `%20` to `+`, which it would do if `contentType` was left at the default value of `application/x-www-form-urlencoded`. If for some reason you must leave `contentType` set to the default, be sure to set `processData` to `false` to prevent this.

The call to `JSON.stringify` could be avoided here, but using it allows us to provide the data in the form of a JavaScript object (thus avoiding embarrassing JSON syntax errors such as failing to quote property names).

All in one examples

Ajax Get:

Solution 1:

```
$.get('url.html', function(data){
    $('#update-box').html(data);
});
```

Solution 2:

```
$.ajax({
    type: 'GET',
    url: 'url.php',
}).done(function(data){
    $('#update-box').html(data);
}).fail(function(jqXHR, textStatus){
    alert('Error occured: ' + textStatus);
});
```

Ajax Load: Another ajax get method created for simplicity

```
$('#update-box').load('url.html');
```

.load can also be called with additional data. The data part can be provided as string or object.

```
$('#update-box').load('url.php', {data: "something"});
$('#update-box').load('url.php', "data=something");
```

If .load is called with a callback method, the request to the server will be a post

```
$('#update-box').load('url.php', {data: "something"}, function(resolve){
    //do something
});
```

Ajax Post:

Solution 1:

```
$.post('url.php',
    {date1Name: data1Value, date2Name: data2Value}, //data to be posted
    function(data){
        $('#update-box').html(data);
    }
);
```

Solution 2:

```
$.ajax({
    type: 'Post',
```

```

        url: 'url.php',
        data: {date1Name: data1Value, date2Name: data2Value} //data to be posted
    }).done(function(data){
        $('#update-box').html(data);
    }).fail(function(jqXHR, textStatus){
        alert('Error occured: ' + textStatus);
    });

```

Ajax Post JSON:

```

var postData = {
    Name: name,
    Address: address,
    Phone: phone
};

$.ajax({
    type: "POST",
    url: "url.php",
    dataType: "json",
    data: JSON.stringify(postData),
    success: function (data) {
        //here variable data is in JSON format
    }
});

```

Ajax Get JSON:

Solution 1:

```

$.getJSON('url.php', function(data){
    //here variable data is in JSON format
});

```

Solution 2:

```

$.ajax({
    type: "Get",
    url: "url.php",
    dataType: "json",
    data: JSON.stringify(postData),
    success: function (data) {
        //here variable data is in JSON format
    },
    error: function(jqXHR, textStatus){
        alert('Error occured: ' + textStatus);
    }
});

```

Ajax Abort a Call or Request

```

var xhr = $.ajax({
    type: "POST",
    url: "some.php",
    data: "name=John&location=Boston",

```

```
    success: function(msg) {  
        alert( "Data Saved: " + msg );  
    }  
});
```

//kill the request

```
xhr.abort()
```

Ajax File Uploads

1. A Simple Complete Example

We could use this sample code to upload the files selected by the user every time a new file selection is made.

```
<input type="file" id="file-input" multiple>
```

```
var files;  
var fdata = new FormData();  
$("#file-input").on("change", function (e) {  
    files = this.files;  
  
    $.each(files, function (i, file) {  
        fdata.append("file" + i, file);  
    });  
  
    fdata.append("FullName", "John Doe");  
    fdata.append("Gender", "Male");  
    fdata.append("Age", "24");  
  
    $.ajax({  
        url: "/Test/Url",  
        type: "post",  
        data: fdata, //add the FormData object to the data parameter  
        processData: false, //tell jquery not to process data  
        contentType: false, //tell jquery not to set content-type  
        success: function (response, status, jqxhr) {  
            //handle success  
        },  
        error: function (jqxhr, status, errorMessage) {  
            //handle error  
        }  
    });  
});
```

Now let's break this down and inspect it part by part.

2. Working With File Inputs

This [MDN Document \(Using files from web applications \)](#) is a good read about various methods on how to handle file inputs. Some of these methods will also be used in this example.

Before we get to uploading files, we first need to give the user a way to select the files they want to upload. For this purpose we will use a `file` input. The `multiple` property allows for selecting more than one files, you can remove it if you want the user to select one file at a time.

```
<input type="file" id="file-input" multiple>
```

We will be using input's `change` event to capture the files.

```
var files;
$("#file-input").on("change", function(e) {
    files = this.files;
});
```

Inside the handler function, we access the files through the `files` property of our input. This gives us a [FileList](#), which is an array like object.

3. Creating and Filling the FormData

In order to upload files with Ajax we are going to use [FormData](#).

```
var fdata = new FormData();
```

[FileList](#) we have obtained in the previous step is an array like object and can be iterated using various methods including [for loop](#), [for...of loop](#) and [jQuery.each](#). We will be sticking with the [jQuery](#) in this example.

```
$.each(files, function(i, file) {
    //...
});
```

We will be using the [append method](#) of `FormData` to add the files into our `formdata` object.

```
$.each(files, function(i, file) {
    fdata.append("file" + i, file);
});
```

We can also add other data we want to send the same way. Let's say we want to send some personal information we have received from the user along with the files. We could add this information into our `formdata` object.

```
fdata.append("FullName", "John Doe");
fdata.append("Gender", "Male");
fdata.append("Age", "24");
//...
```

4. Sending the Files With Ajax

```
$.ajax({
  url: "/Test/Url",
  type: "post",
  data: fdata, //add the FormData object to the data parameter
  processData: false, //tell jquery not to process data
  contentType: false, //tell jquery not to set content-type
  success: function (response, status, jqxhr) {
    //handle success
  },
  error: function (jqxhr, status, errorMessage) {
    //handle error
  }
});
```

We set `processData` and `contentType` properties to `false`. This is done so that the files can be send to the server and be processed by the server correctly.

Read Ajax online: <https://riptutorial.com/jquery/topic/316/ajax>

Chapter 3: Append

Syntax

1. `$(selector).append(content)`
2. `$(content).appendTo(selector)`

Parameters

Parameters	Details
content	Possible types: Element, HTML string, text, array, object or even a function returning a string.

Remarks

- `.append()` & `.after()` can potentially execute code. This can occur by injection of script tags or use of HTML attributes that execute code (for example, `<script>`). Do not use these methods to insert strings obtained from untrusted sources such as URL query parameters, cookies, or form inputs. Doing so can introduce cross-site-scripting (XSS) vulnerabilities. Remove or escape any user input before adding content to the document.
- jQuery doesn't officially support SVG. Using jQuery methods on SVG documents, unless explicitly documented for that method, might cause unexpected behaviors. Examples of methods that support SVG as of jQuery 3.0 are `addClass` and `removeClass`.

Examples

Appending an element to a container

Solution 1:

```
$('#parent').append($('#child'));
```

Solution 2:

```
$('#child').appendTo($('#parent'));
```

Both solutions are appending the element `#child` (adding at the end) to the element `#parent`.

Before:

```
<div id="parent">
  <span>other content</span>
</div>
<div id="child">

</div>
```

After:

```
<div id="parent">
  <span>other content</span>
  <div id="child">

  </div>
</div>
```

Note: When you append content that already exists in the document, this content will be removed from its original parent container and appended to the new parent container. So you can't use `.append()` or `.appendTo()` to clone an element. If you need a clone use `.clone()` -> [<http://api.jquery.com/clone/>][1]

Efficient consecutive `.append()` usage

Starting out:

HTML

```
<table id='my-table' width='960' height='500'></table>
```

JS

```
var data = [
  { type: "Name", content: "John Doe" },
  { type: "Birthdate", content: "01/01/1970" },
  { type: "Salary", content: "$40,000,000" },
  // ...300 more rows...
  { type: "Favorite Flavour", content: "Sour" }
];
```

Appending inside a loop

You just received a big array of data. Now it's time to loop through and render it on the page.

Your first thought may be to do something like this:

```
var i; // <- the current item number
var count = data.length; // <- the total
```

```

var row;                                // <- for holding a reference to our row object

// Loop over the array
for ( i = 0; i < count; ++i ) {
    row = data[ i ];

    // Put the whole row into your table
    $('#my-table').append(
        $('<tr></tr>').append(
            $('<td></td>').html(row.type),
            $('<td></td>').html(row.content)
        )
    );
}

```

This is *perfectly valid* and will render exactly what you'd expect, but...

DO NOT do this.

Remember those **300+** rows of data?

Each one will force the browser to re-calculate every element's width, height and positioning values, along with any other styles - unless they are separated by a [layout boundary](#), which unfortunately for this example (as they are descendants of a `<table>` element), they cannot.

At small amounts and few columns, this performance penalty will certainly be negligible. But we want every millisecond to count.

Better options

1. Add to a separate array, append after loop completes

```

/**
 * Repeated DOM traversal (following the tree of elements down until you reach
 * what you're looking for - like our <table>) should also be avoided wherever possible.
 */

// Keep the table cached in a variable then use it until you think it's been removed
var $myTable = $('#my-table');

// To hold our new <tr> jQuery objects
var rowElements = [];

var count = data.length;
var i;
var row;

// Loop over the array
for ( i = 0; i < count; ++i ) {
    rowElements.push(
        $('<tr></tr>').append(
            $('<td></td>').html(row.type),
            $('<td></td>').html(row.content)
        )
    );
}

```

```

    )
  );
}

// Finally, insert ALL rows at once
$myTable.append(rowElements);

```

Out of these options, this one relies on jQuery the most.

2. Using modern Array.* methods

```

var $myTable = $('#my-table');

// Looping with the .map() method
// - This will give us a brand new array based on the result of our callback function
var rowElements = data.map(function ( row ) {

    // Create a row
    var $row = $('<tr></tr>');

    // Create the columns
    var $type = $('<td></td>').html(row.type);
    var $content = $('<td></td>').html(row.content);

    // Add the columns to the row
    $row.append($type, $content);

    // Add to the newly-generated array
    return $row;
});

// Finally, put ALL of the rows into your table
$myTable.append(rowElements);

```

Functionally equivalent to the one before it, only easier to read.

3. Using strings of HTML (instead of jQuery built-in methods)

```

// ...
var rowElements = data.map(function ( row ) {
    var rowHTML = '<tr><td>';
    rowHTML += row.type;
    rowHTML += '</td><td>';
    rowHTML += row.content;
    rowHTML += '</td></tr>';
    return rowHTML;
});

// Using .join('') here combines all the separate strings into one
$myTable.append(rowElements.join(''));

```

Perfectly valid but again, **not recommended**. This forces jQuery to parse a very large amount of text at once and is not necessary. jQuery is very good at what it does when used correctly.

4. Manually create elements, append to document fragment

```
var $myTable = $(document.getElementById('my-table'));

/**
 * Create a document fragment to hold our columns
 * - after appending this to each row, it empties itself
 *   so we can re-use it in the next iteration.
 */
var colFragment = document.createDocumentFragment();

/**
 * Loop over the array using .reduce() this time.
 * We get a nice, tidy output without any side-effects.
 * - In this example, the result will be a
 *   document fragment holding all the <tr> elements.
 */
var rowFragment = data.reduce(function ( fragment, row ) {

    // Create a row
    var rowEl = document.createElement('tr');

    // Create the columns and the inner text nodes
    var typeEl = document.createElement('td');
    var typeText = document.createTextNode(row.type);
    typeEl.appendChild(typeText);

    var contentEl = document.createElement('td');
    var contentText = document.createTextNode(row.content);
    contentEl.appendChild(contentText);

    // Add the columns to the column fragment
    // - this would be useful if columns were iterated over separately
    //   but in this example it's just for show and tell.
    colFragment.appendChild(typeEl);
    colFragment.appendChild(contentEl);

    rowEl.appendChild(colFragment);

    // Add rowEl to fragment - this acts as a temporary buffer to
    // accumulate multiple DOM nodes before bulk insertion
    fragment.appendChild(rowEl);

    return fragment;
}, document.createDocumentFragment());

// Now dump the whole fragment into your table
$myTable.append(rowFragment);
```

My personal favorite. This illustrates a general idea of what jQuery does at a lower level.

jQuery append

HTML

```
<p>This is a nice </p>
<p>I like </p>

<ul>
  <li>List item 1</li>
  <li>List item 2</li>
  <li>List item 3</li>
</ul>

<button id="btn-1">Append text</button>
<button id="btn-2">Append list item</button>
```

Script

```
$("#btn-1").click(function(){
  $("p").append(" <b>Book</b>.");
});
$("#btn-2").click(function(){
  $("ul").append("<li>Appended list item</li>");
});
});
```

Read Append online: <https://riptutorial.com/jquery/topic/1910/append>

Chapter 4: Attributes

Remarks

The jQuery function `.attr()`, gets the value of an attribute for the **first** element in the set of matched elements or set one or more attributes for **every** matched element.

It is worth noting that when getting the value of an attribute, it only gets it from the first element that matches the selector (i.e. `$("input").attr("type");` would only get the type of the first input, if there are more than one)

However, when setting an attribute, it will apply it to all matching elements.

Examples

Get the attribute value of a HTML element

When a single parameter is passed to the `.attr()` function it returns the value of passed attribute on the selected element.

Syntax:

```
$([selector]).attr([attribute name]);
```

Example:

HTML:

```
<a href="/home">Home</a>
```

jQuery:

```
$('a').attr('href');
```

Fetching data attributes:

jQuery offers `.data()` function in order to deal with data attributes. `.data` function returns the value of the data attribute on the selected element.

Syntax:

```
$([selector]).data([attribute name]);
```

Example:

Html:

```
<article data-column="3"></article>
```

jQuery:

```
$("#article").data("column")
```

Note:

jQuery's `data()` method will give you access to `data-*` attributes, BUT, it clobbers the case of the attribute name. [Reference](#)

Setting value of HTML attribute

If you want to add an attribute to some element you can use the `attr(attributeName, attributeValue)` function. For example:

```
$('#a').attr('title', 'Click me');
```

This example will add mouseover text "Click me" to all links on the page.

The same function is used to change attributes' values.

Removing attribute

To remove an attribute from an element you can use the function `.removeAttr(attributeName)`. For example:

```
$('#home').removeAttr('title');
```

This will remove `title` attribute from the element with ID `home`.

Difference between `attr()` and `prop()`

`attr()` gets/sets the HTML attribute using the DOM functions `getAttribute()` and `setAttribute()`. `prop()` works by setting the DOM property without changing the attribute. In many cases the two are interchangeable, but occasionally one is needed over the other.

To set a checkbox as checked:

```
$('#tosAccept').prop('checked', true); // using attr() won't work properly here
```

To remove a property you can use the `removeProp()` method. Similarly `removeAttr()` removes attributes.

Read Attributes online: <https://riptutorial.com/jquery/topic/4429/attributes>

Chapter 5: Checkbox Select all with automatic check/uncheck on other checkbox change

Introduction

I've used various Stackoverflow examples and answers to come to this really simple example on how to manage "select all" checkbox coupled with an automatic check/uncheck if any of the group checkbox status changes. Constraint: The "select all" id must match the input names to create the select all group. In the example, the input select all ID is cbGroup1. The input names are also cbGroup1

Code is very short, not plenty of if statement (time and resource consuming).

Examples

2 select all checkboxes with corresponding group checkboxes

```
<script src="https://ajax.googleapis.com/ajax/libs/jquery/3.2.1/jquery.min.js"></script>

<p>
<input id="cbGroup1" type="checkbox">Select all
<input name="cbGroup1" type="checkbox" value="value1_1">Group1 value 1
<input name="cbGroup1" type="checkbox" value="value1_2">Group1 value 2
<input name="cbGroup1" type="checkbox" value="value1_3">Group1 value 3
</p>
<p>
<input id="cbGroup2" type="checkbox">Select all
<input name="cbGroup2" type="checkbox" value="value2_1">Group2 value 1
<input name="cbGroup2" type="checkbox" value="value2_2">Group2 value 2
<input name="cbGroup2" type="checkbox" value="value2_3">Group2 value 3
</p>

<script type="text/javascript" language="javascript">
    $("input").change(function() {
        $('input[name="'+this.id+'"]').not(this).prop('checked', this.checked);
        $('#'+this.name).prop('checked', $('input[name="'+this.name+'"]').length ===
        $('input[name="'+this.name+'"]').filter(':checked').length);
    });
</script>
```

Read Checkbox Select all with automatic check/uncheck on other checkbox change online:
<https://riptutorial.com/jquery/topic/10076/checkbox-select-all-with-automatic-check-uncheck-on-other-checkbox-change>

Chapter 6: CSS Manipulation

Syntax

- `.css( cssProperty )` // Get the rendered CSS property value
- `.css( [cssProperty , ...] )` // Get values from Array of cssProperties
- `.css( cssProperty, value )` // Set value
- `.css( {cssProperty:value, ...} )` // Set properties and values
- `.css( cssProperty, function )` // Expose the cssProperty to a callback function

Remarks

Rendered values

If a responsive unit is used (like `"auto"`, `"%"`, `"vw"` etc.), `.css()` will return the actual rendered value in `px`

```
.myElement{ width: 20%; }
```

```
var width = $(".myElement").css("width"); // "123px"
```

Formatting properties and values

Properties can be defined using **standard CSS formatting as String** or using **camelCase**

```
"margin-bottom"  
marginBottom
```

Values should be expressed in String. Numeric values are treated as `px` units internally by jQuery

```
.css(fontSize: "1em")  
.css(fontSize: "16px")  
.css(fontSize: 16)      // px will be used
```

As of jQuery 3 avoid using `.show()` and `.hide()`

According to [this jQuery Blog post](#), due to overhead and performance issues, you should no longer be using `.show()` or `.hide()`.

If you have elements in a stylesheet that are set to `display: none`, the `.show()` method will no longer override that. So the most important rule for moving to jQuery 3.0 is this: Don't use a stylesheet to set the default of `display: none` and then try to use `.show()` – or any method that shows elements, such as `.slideDown()` and `.fadeIn()` – to make it visible. If you need an element to be hidden by default, the best way is to add a class

name like “hidden” to the element and define that class to be `display: none` in a stylesheet. Then you can add or remove that class using jQuery’s `.addClass()` and `.removeClass()` methods to control visibility. Alternately, you can have a `.ready()` handler call `.hide()` on the elements before they are displayed on the page. Or, if you really must retain the stylesheet default, you can use `.css("display", "block")` (or the appropriate display value) to override the stylesheet.

Examples

Set CSS property

Setting only one style:

```
$('#target-element').css('color', '#000000');
```

Setting multiple styles at the same time:

```
$('#target-element').css({
  'color': '#000000',
  'font-size': '12pt',
  'float': 'left',
});
```

Get CSS property

To get an element's CSS property you can use the `.css(propertyName)` method:

```
var color = $('#element').css('color');
var fontSize = $('#element').css('font-size');
```

Increment/Decrement Numeric Properties

Numeric CSS properties can be incremented and decremented with the `+=` and `-=` syntax, respectively, using the `.css()` method:

```
// Increment using the += syntax
$("#target-element").css("font-size", "+=10");

// You can also specify the unit to increment by
$("#target-element").css("width", "+=100pt");
$("#target-element").css("top", "+=30px");
$("#target-element").css("left", "+=3em");

// Decrementing is done by using the -= syntax
$("#target-element").css("height", "-=50pt");
```

CSS – Getters and Setters

CSS Getter

The `.css()` **getter** function can be applied to every DOM element on the page like the following:

```
// Rendered width in px as a string. ex: `150px`  
// Notice the `as a string` designation - if you require a true integer,  
// refer to `$.width()` method  
$("body").css("width");
```

This line will return the **computed width** of the specified element, each CSS property you provide in the parentheses will yield the value of the property for this `$(".selector")` DOM element, if you ask for CSS attribute that doesn't exist you will get `undefined` as a response.

You also can call the **CSS getter** with an array of attributes:

```
$(".body").css(["animation", "width"]);
```

this will return an object of all the attributes with their values:

```
Object {animation: "none 0s ease 0s 1 normal none running", width: "529px"}
```

CSS Setter

The `.css()` **setter** method can also be applied to every DOM element on the page.

```
$(".selector").css("width", 500);
```

This statement set the `width` of the `$(".selector")` to `500px` and return the jQuery object so you can chain more methods to the specified selector.

The `.css()` **setter** can also be used passing an Object of CSS properties and values like:

```
$(".body").css({"height": "100px", width:100, "padding-top":40, paddingBottom:"2em"});
```

All the changes the setter made are appended to the DOM element `style` property thus affecting the elements' styles (unless that style property value is already defined as `!important` somewhere else in styles).

Read CSS Manipulation online: <https://riptutorial.com/jquery/topic/2732/css-manipulation>

Chapter 7: document-ready event

Examples

What is document-ready and how should I use it?

jQuery code is often wrapped in `jQuery(function($){ ... });` so that it only runs after the DOM has finished loading.

```
<script type="text/javascript">
  jQuery(function($){
    // this will set the div's text to "Hello".
    $("#myDiv").text("Hello");
  });
</script>

<div id="myDiv">Text</div>
```

This is important because jQuery (and JavaScript generally) cannot select a DOM element that has not been rendered to the page.

```
<script type="text/javascript">
  // no element with id="myDiv" exists at this point, so $("#myDiv") is an
  // empty selection, and this will have no effect
  $("#myDiv").text("Hello");
</script>

<div id="myDiv">Text</div>
```

Note that you can alias the jQuery namespace by passing a custom handler into the `.ready()` method. This is useful for cases when another JS library is using the same shortened `$` alias as *jQuery*, which create a conflict. To avoid this conflict, you must call `$.noConflict();` - This forcing you to use only the default *jQuery* namespace (Instead of the short `$` alias).

By passing a custom handler to the `.ready()` handler, you will be able to choose the alias name to use *jQuery*.

```
$.noConflict();

jQuery( document ).ready(function( $ ) {
  // Here we can use '$' as jQuery alias without it conflicting with other
  // libraries that use the same namespace
  $('body').append('<div>Hello</div>')
});

jQuery( document ).ready(function( jq ) {
  // Here we use a custom jQuery alias 'jq'
  jq('body').append('<div>Hello</div>')
});
```

Rather than simply putting your jQuery code at the bottom of the page, using the `$(document).ready`

function ensures that all HTML elements have been rendered and the entire Document Object Model (DOM) is ready for JavaScript code to execute.

jQuery 2.2.3 and earlier

These are all equivalent, the code inside the blocks will run when the document is ready:

```
$(function() {  
    // code  
});  
  
$.ready(function() {  
    // code  
});  
  
$(document).ready(function() {  
    // code  
});
```

Because these are equivalent the first is the recommended form, the following is a version of that with the `jQuery` keyword instead of the `$` which produce the same results:

```
jQuery(function() {  
    // code  
});
```

jQuery 3.0

Notation

As of jQuery 3.0, only this form is recommended:

```
jQuery(function($) {  
    // Run when document is ready  
    // $ (first argument) will be internal reference to jQuery  
    // Never rely on $ being a reference to jQuery in the global namespace  
});
```

All other document-ready handlers [are deprecated in jQuery 3.0](#).

Asynchronous

As of jQuery 3.0, the ready handler [will always be called asynchronously](#). This means that in the code below, the log 'outside handler' will always be displayed first, regardless whether the document was ready at the point of execution.

```
$(function() {  
    console.log("inside handler");  
});  
console.log("outside handler");
```

- > outside handler
- > inside handler

Difference between `$(document).ready()` and `$(window).load()`

`$(window).load()` was **deprecated in jQuery version 1.8** (and completely removed from **jQuery 3.0**) and as such should not be used anymore. The reasons for the deprecation are noted on the [jQuery page about this event](#)

Caveats of the load event when used with images

A common challenge developers attempt to solve using the `.load()` shortcut is to execute a function when an image (or collection of images) have completely loaded. There are several known caveats with this that should be noted. These are:

- It doesn't work consistently nor reliably cross-browser
- It doesn't fire correctly in WebKit if the image `src` is set to the same `src` as before
- It doesn't correctly bubble up the DOM tree
- Can cease to fire for images that already live in the browser's cache

If you still wish to use `load()` it is documented below:

`$(document).ready()` waits until the full DOM is available -- all the elements in the HTML have been parsed and are in the document. However, resources such as images may not have fully loaded at this point. If it is important to wait until all resources are loaded, `$(window).load()` **and you're aware of the significant limitations of this event** then the below can be used instead:

```
$(document).ready(function() {
    console.log($("#my_large_image").height()); // may be 0 because the image isn't available
});

$(window).load(function() {
    console.log($("#my_large_image").height()); // will be correct
});
```

Attaching events and manipulating the DOM inside `ready()`

Example uses of `$(document).ready()`:

1. Attaching event handlers

Attach jQuery event handlers

```
$(document).ready(function() {
    $("button").click(function() {
        // Code for the click function
    });
});
```

2. Run jQuery code after the page structure is created

```
jQuery(function($) {  
  // set the value of an element.  
  $("#myElement").val("Hello");  
});
```

3. Manipulate the loaded DOM structure

For example: hide a `div` when the page loads for the first time and show it on the click event of a button

```
$(document).ready(function() {  
  $("#toggleDiv").hide();  
  $("button").click(function() {  
    $("#toggleDiv").show();  
  });  
});
```

Difference between `jQuery(fn)` and executing your code before

Using the document-ready event can have small [performance drawbacks](#), with delayed execution of up to ~300ms. Sometimes the same behavior can be achieved by execution of code just before the closing `</body>` tag:

```
<body>  
  <span id="greeting"></span> world!  
  <script>  
    $("#greeting").text("Hello");  
  </script>  
</body>
```

will produce similar behavior but perform sooner than as it does not wait for the document ready event trigger as it does in:

```
<head>  
  <script>  
    jQuery(function($) {  
      $("#greeting").text("Hello");  
    });  
  </script>  
</head>  
<body>  
  <span id="greeting"></span> world!  
</body>
```

Emphasis on the fact that first example relies upon your knowledge of your page and placement of the script just prior to the closing `</body>` tag and specifically after the `span` tag.

Read document-ready event online: <https://riptutorial.com/jquery/topic/500/document-ready-event>

Chapter 8: DOM Manipulation

Examples

Creating DOM elements

The `jQuery` function (usually aliased as `$`) can be used both to select elements and to create new elements.

```
var myLink = $('<a href="http://stackexchange.com"></a>');
```

You can optionally pass a second argument with element attributes:

```
var myLink = $('<a>', { 'href': 'http://stackexchange.com' });
```

'<a>' --> The first argument specifies the type of DOM element you want to create. In this example it's an [anchor](#) but could be anything [on this list](#). See the [specification](#) for a reference of the `a` element.

{ 'href': 'http://stackexchange.com' } --> the second argument is a [JavaScript Object](#) containing attribute name/value pairs.

the 'name': 'value' pairs will appear between the `< >` of the first argument, for example `<a name:value>` which for our example would be `<a href="http://stackexchange.com"></a>`

Manipulating element classes

Assuming the page includes an HTML element like:

```
<p class="small-paragraph">
  This is a small <a href="https://en.wikipedia.org/wiki/Paragraph">paragraph</a>
  with a <a class="trusted" href="http://stackexchange.com">link</a> inside.
</p>
```

`jQuery` provides useful functions to manipulate DOM classes, most notably `hasClass()`, `addClass()`, `removeClass()` and `toggleClass()`. These functions directly modify the `class` attribute of the matched elements.

```
$('p').hasClass('small-paragraph'); // true
$('p').hasClass('large-paragraph'); // false

// Add a class to all links within paragraphs
$('p a').addClass('untrusted-link-in-paragraph');

// Remove the class from a.trusted
$('a.trusted.untrusted-link-in-paragraph')
  .removeClass('untrusted-link-in-paragraph')
  .addClass('trusted-link-in-paragraph');
```

Toggle a class

Given the example markup, we can add a class with our first `.toggleClass()`:

```
$(".small-paragraph").toggleClass("pretty");
```

Now this would return `true`: `$(".small-paragraph").hasClass("pretty")`

`toggleClass` provides the same effect with less code as:

```
if($(".small-paragraph").hasClass("pretty")){
    $(".small-paragraph").removeClass("pretty");}
else {
    $(".small-paragraph").addClass("pretty"); }
```

`toggle` Two classes:

```
$(".small-paragraph").toggleClass("pretty cool");
```

Boolean to add/remove classes:

```
$(".small-paragraph").toggleClass("pretty",true); //cannot be truthy/falsey

$(".small-paragraph").toggleClass("pretty",false);
```

Function for class toggle (see example further down to avoid an issue)

```
$( "div.surface" ).toggleClass(function() {
    if ( $( this ).parent().is( ".water" ) ) {
        return "wet";
    } else {
        return "dry";
    }
});
```

Used in examples:

```
// functions to use in examples
function stringContains(myString, mySubString) {
    return myString.indexOf(mySubString) !== -1;
}
function isOdd(num) { return num % 2;}
var showClass = true; //we want to add the class
```

Examples:

Use the element index to toggle classes odd/even

```
$( "div.gridrow" ).toggleClass(function(index,oldClasses, false), showClass ) {
    showClass
    if ( isOdd(index) ) {
        return "wet";
```

```

    } else {
        return "dry";
    }
});

```

More complex `toggleClass` example, given a simple grid markup

```

<div class="grid">
  <div class="gridrow">row</div>
  <div class="gridrow">row</div>
  <div class="gridrow">row</div>
  <div class="gridrow">row</div>
  <div class="gridrow">row</div>
  <div class="gridrow gridfooter">row but I am footer!</div>
</div>

```

Simple functions for our examples:

```

function isOdd(num) {
    return num % 2;
}

function stringContains(myString, mySubString) {
    return myString.indexOf(mySubString) !== -1;
}

var showClass = true; //we want to add the class

```

Add an odd/even class to elements with a `gridrow` class

```

$("div.gridrow").toggleClass(function(index, oldClasses, showThisClass) {
    if (isOdd(index)) {
        return "odd";
    } else {
        return "even";
    }
    return oldClasses;
}, showClass);

```

If the row has a `gridfooter` class, remove the odd/even classes, keep the rest.

```

$("div.gridrow").toggleClass(function(index, oldClasses, showThisClass) {
    var isFooter = stringContains(oldClasses, "gridfooter");
    if (isFooter) {
        oldClasses = oldClasses.replace('even', ' ').replace('odd', ' ');
        $(this).toggleClass("even odd", false);
    }
    return oldClasses;
}, showClass);

```

The classes that get returned are what is effected. Here, if an element does not have a `gridfooter`, add a class for even/odd. This example illustrates the return of the OLD class list. If this `else return oldClasses;` is removed, only the new classes get added, thus the row with a `gridfooter` class would have all classes removed had we not returned those old ones - they would have been toggled (removed) otherwise.

```

$("div.gridrow").toggleClass(function(index, oldClasses, showThisClass) {
    var isFooter = stringContains(oldClasses, "gridfooter");
    if (!isFooter) {
        if (isOdd(index)) {
            return "oddLight";
        } else {
            return "evenLight";
        }
    } else return oldClasses;
}, showClass);

```

Other API Methods

jQuery offers a variety of methods that can be used for DOM manipulation.

The first is the `.empty()` method.

Imagine the following markup:

```

<div id="content">
  <div>Some text</div>
</div>

```

By calling `$('#content').empty();`, the inner div would be removed. This could also be achieved by using `$('#content').html('');`

Another handy function is the `.closest()` function:

```

<tr id="row_1">
  <td><button type="button" class="delete">Delete</button>
</tr>

```

If you wanted to find the closest row to a button that was clicked within one of the row cells then you could do this:

```

$('.delete').click(function() {
    $(this).closest('tr');
});

```

Since there will probably be multiple rows, each with their own `delete` buttons, we use `$(this)` within the `.click()` function to limit the scope to the button we actually clicked.

If you wanted to get the `id` of the row containing the `Delete` button that you clicked, you could do something like this:

```

$('.delete').click(function() {
    var $row = $(this).closest('tr');
    var id = $row.attr('id');
});

```

It is usually considered good practise to prefix variables containing jQuery objects with a `$` (dollar

sign) to make it clear what the variable is.

An alternative to `.closest()` is the `.parents()` method:

```
$('.delete').click(function() {  
    var $row = $(this).parents('tr');  
    var id = $row.attr('id');  
});
```

and there is also a `.parent()` function as well:

```
$('.delete').click(function() {  
    var $row = $(this).parent().parent();  
    var id = $row.attr('id');  
});
```

`.parent()` only goes up one level of the DOM tree so it is quite inflexible, if you were to change the delete button to be contained within a `span` for example, then the jQuery selector would be broken.

`.html()`

You can use this method to replace all of the HTML within the selector. Assuming you have an html element like this

```
<div class="row">  
    <div class="col-md-12">  
        <div id="information">  
            <p>Old message</p>  
        </div>  
    </div>  
</div>
```

You could use `.html()` to remove and add an alert or informational text to alert users all with one line.

```
$("#information").html("<p>This is the new alert!</p>");
```

Sorting elements

To sort elements efficiently (all at once and with minimal DOM interruption), we need to:

1. **Find** the elements
2. **Sort** based on a set condition
3. **Insert** back in the DOM

```
<ul id='my-color-list'>  
    <li class="disabled">Red</li>  
    <li>Green</li>  
    <li class="disabled">Purple</li>  
    <li>Orange</li>  
</ul>
```

1. Find them - `.children()` or `.find()`

This will give us back an Array-like object to play with.

```
var $myColorList = $('#my-color-list');

// Elements one layer deep get .children(), any deeper go with .find()
var $colors = $myColorList.children('li');
```

2. Re-arrange them - `Array.prototype.sort()`

This is currently setup to return the elements in Ascending order based on the HTML content (aka their colors).

```
/**
 * Bind $colors to the sort method so we don't have to travel up
 * all these properties more than once.
 */
var sortList = Array.prototype.sort.bind($colors);

sortList(function ( a, b ) {

    // Cache inner content from the first element (a) and the next sibling (b)
    var aText = a.innerHTML;
    var bText = b.innerHTML;

    // Returning -1 will place element `a` before element `b`
    if ( aText < bText ) {
        return -1;
    }

    // Returning 1 will do the opposite
    if ( aText > bText ) {
        return 1;
    }

    // Returning 0 leaves them as-is
    return 0;
});
```

3. Insert them - `.append()`

Note that we don't need to detach the elements first - `append()` will move elements that already exist in the DOM, so we won't have extra copies

```
// Put it right back where we got it
$myColorList.append($colors);
```

Make it cute

Add a sort button

```
<!-- previous HTML above -->
<button type='button' id='btn-sort'>
  Sort
</button>
```

Set the initial value of sorting direction

```
var ascending = true;
```

Cache our DOM elements and `sortList()` out here to minimize our DOM processing

```
var $myColorList = $('#my-color-list');
var $colors = $myColorList.children('li');
var sortList = Array.prototype.sort.bind($colors);
```

Wrap everything up in a `doSort()` function

```
// Put the sortList() and detach/append calls in this portable little thing
var doSort = function ( ascending ) {

  sortList(function ( a, b ) {
    // ...
  });

  $myColorList.append($colors);
};
```

Add click handler for `$('#btn-sort')`

```
$('#btn-sort').on('click', function () {
  // Run the sort and pass in the direction value
  doSort(ascending);

  // Toggle direction and save
  ascending = !ascending;
});
```

All together now

```
var ascending = true;

var $myColorList = $('#my-color-list');
var $colors = $myColorList.children('li');
var sortList = Array.prototype.sort.bind($colors);

var doSort = function ( ascending ) {
```

```

sortList(function ( a, b ) {

    var aText = a.innerHTML;
    var bText = b.innerHTML;

    if ( aText < bText ) {
        return ascending ? -1 : 1;
    }

    if ( aText > bText ) {
        return ascending ? 1 : -1;
    }

    return 0;
});

$myColorList.append($colors);

};

$('#btn-sort').on('click', function () {
    doSort(ascending);
    ascending = !ascending;
});

```

Bonus

Multi-level sorting (grouping sorted elements)

```

// ...

var doSort = function ( ascending ) {

    sortList(function ( a, b ) {

        // ...initial sorting...

    }).sort(function ( a, b ) {

        // We take the returned items and sort them once more
        var aClass = a.className;
        var bClass = b.className;

        // Let's group the disabled items together and put them at the end

        /**
         * If the two elements being compared have the same class
         * then there's no need to move anything.
         */
        if ( aClass !== bClass ) {
            return aClass === 'disabled' ? 1 : -1;
        }
        return 0;
    });

    // And finalize with re-insert
    $myColorList.append($colors);

```

```
};  
// ...
```

Can you take it one step further?

Add another button to toggle disabled group sorting

[MDN - Array.prototype.sort\(\)](#)

Read DOM Manipulation online: <https://riptutorial.com/jquery/topic/512/dom-manipulation>

Chapter 9: DOM Traversing

Examples

Select children of element

To select the children of an element you can use the `children()` method.

```
<div class="parent">
  <h2>A headline</h2>
  <p>Lorem ipsum dolor sit amet...</p>
  <p>Praesent quis dolor turpis...</p>
</div>
```

Change the color of *all* the children of the `.parent` element:

```
$('.parent').children().css("color", "green");
```

The method accepts an optional `selector` argument that can be used to filter the elements that are returned.

```
// Only get "p" children
$('.parent').children("p").css("color", "green");
```

Iterating over list of jQuery elements

When you need to iterate over the list of jQuery elements.

Consider this DOM structure:

```
<div class="container">
  <div class="red one">RED 1 Info</div>
  <div class="red two">RED 2 Info</div>
  <div class="red three">RED 3 Info</div>
</div>
```

To print the text present in all the `div` elements with a class of `red`:

```
$(".red").each(function(key, ele){
  var text = $(ele).text();
  console.log(text);
});
```

Tip: `key` is the index of the `div.red` element we're currently iterating over, within its parent. `ele` is the HTML element, so we can create a jQuery object from it using `$()` or `jQuery()`, like so: `$(ele)`. After, we can call any jQuery method on the object, like `css()` or `hide()` etc. In this example, we just pull the text of the object.

Selecting siblings

To select siblings of an item you can use the `.siblings()` method.

A typical example where you want to modify the siblings of an item is in a menu:

```
<ul class="menu">
  <li class="selected">Home</li>
  <li>Blog</li>
  <li>About</li>
</ul>
```

When the user clicks on a menu item the `selected` class should be added to the clicked element and removed from its *siblings*:

```
$(".menu").on("click", "li", function () {
  $(this).addClass("selected");
  $(this).siblings().removeClass("selected");
});
```

The method takes an optional `selector` argument, which can be used if you need to narrow down the kinds of siblings you want to select:

```
$(this).siblings("li").removeClass("selected");
```

closest() method

Returns the first element that matches the selector starting at the element and traversing up the DOM tree.

HTML

```
<div id="abc" class="row">
  <div id="xyz" class="row">
  </div>
  <p id="origin">
    Hello
  </p>
</div>
```

jQuery

```
var target = $('#origin').closest('.row');
console.log("Closest row:", target.attr('id') );

var target2 = $('#origin').closest('p');
console.log("Closest p:", target2.attr('id') );
```

OUTPUT

```
"Closest row: abc"
```

```
"Closest p: origin"
```

first() method : The first method returns the first element from the matched set of elements.

HTML

```
<div class='.firstExample'>
  <p>This is first paragraph in a div.</p>
  <p>This is second paragraph in a div.</p>
  <p>This is third paragraph in a div.</p>
  <p>This is fourth paragraph in a div.</p>
  <p>This is fifth paragraph in a div.</p>
</div>
```

JQuery

```
var firstParagraph = $("div p").first();
console.log("First paragraph:", firstParagraph.text());
```

Output:

```
First paragraph: This is first paragraph in a div.
```

Get next element

To get the next element you can use the `.next()` method.

```
<ul>
  <li>Mark</li>
  <li class="anna">Anna</li>
  <li>Paul</li>
</ul>
```

If you are standing on the "Anna" element and you want to get the next element, "Paul", the `.next()` method will allow you to do that.

```
// "Paul" now has green text
$(".anna").next().css("color", "green");
```

The method takes an optional `selector` argument, which can be used if the next element must be a certain kind of element.

```
// Next element is a "li", "Paul" now has green text
$(".anna").next("li").css("color", "green");
```

If the next element is not of the type `selector` then an empty set is returned, and the modifications will not do anything.

```
// Next element is not a ".mark", nothing will be done in this case
$(".anna").next(".mark").css("color", "green");
```

Get previous element

To get the previous element you can use the `.prev()` method.

```
<ul>
  <li>Mark</li>
  <li class="anna">Anna</li>
  <li>Paul</li>
</ul>
```

If you are standing on the "Anna" element and you want to get the previous element, "Mark", the `.prev()` method will allow you to do that.

```
// "Mark" now has green text
$(".anna").prev().css("color", "green");
```

The method takes an optional `selector` argument, which can be used if the previous element must be a certain kind of element.

```
// Previous element is a "li", "Mark" now has green text
$(".anna").prev("li").css("color", "green");
```

If the previous element is not of the type `selector` then an empty set is returned, and the modifications will not do anything.

```
// Previous element is not a ".paul", nothing will be done in this case
$(".anna").prev("paul").css("color", "green");
```

Filter a selection

To filter a selection you can use the `.filter()` method.

The method is called on a selection and returns a new selection. If the filter matches an element then it is added to the returned selection, otherwise it is ignored. If no element is matched then an empty selection is returned.

The HTML

This is the HTML we will be using.

```
<ul>
  <li class="zero">Zero</li>
  <li class="one">One</li>
  <li class="two">Two</li>
  <li class="three">Three</li>
</ul>
```

Selector

Filtering using **selectors** is one of the simpler ways to filter a selection.

```
$("#li").filter(":even").css("color", "green"); // Color even elements green
$("#li").filter(":one").css("font-weight", "bold"); // Make ".one" bold
```

Function

Filtering a selection using a **function** is useful if it is not possible to use selectors.

The function is called for each element in the selection. If it returns a `true` value then the element will be added to the returned selection.

```
var selection = $("#li").filter(function (index, element) {
    // "index" is the position of the element
    // "element" is the same as "this"
    return $(this).hasClass("two");
});
selection.css("color", "green"); // ".two" will be colored green
```

Elements

You can filter by DOM elements. If the DOM elements are in the selection then they will be included in the returned selection.

```
var three = document.getElementsByClassName("three");
$("#li").filter(three).css("color", "green");
```

Selection

You can also filter a selection by another selection. If an element is in both selections then it will be included in the returned selection.

```
var elems = $(".one, .three");
$("#li").filter(elems).css("color", "green");
```

find() method

`.find()` method allows us to search through the descendants of these elements in the DOM tree and construct a new jQuery object from the matching elements.

HTML

```
<div class="parent">
  <div class="children" name="first">
    <ul>
      <li>A1</li>
      <li>A2</li>
      <li>A3</li>
```

```
        </ul>
    </div>
    <div class="children" name="second">
        <ul>
            <li>B1</li>
            <li>B2</li>
            <li>B3</li>
        </ul>
    </div>
</div>
```

jQuery

```
$('.parent').find('.children[name="second"] ul li').css('font-weight','bold');
```

Output

- A1
- A2
- A3
- **B1**
- **B2**
- **B3**

Read DOM Traversing online: <https://riptutorial.com/jquery/topic/1189/dom-traversing>

Chapter 10: Each function

Examples

Basic use

```
// array
var arr = [
  'one',
  'two',
  'three',
  'four'
];
$.each(arr, function (index, value) {
  console.log(value);

  // Will stop running after "three"
  return (value !== 'three');
});
// Outputs: one two three
```

jQuery each function

HTML:

```
<ul>
  <li>Mango</li>
  <li>Book</li>
</ul>
```

Script:

```
$( "li" ).each(function( index ) {
  console.log( index + ": " + $( this ).text() );
});
```

A message is thus logged for each item in the list:

0: Mango

1: Book

Read Each function online: <https://riptutorial.com/jquery/topic/10853/each-function>

Chapter 11: Element Visibility

Parameters

Parameter	Details
Duration	When passed, the effects of <code>.hide()</code> , <code>.show()</code> and <code>.toggle()</code> are animated; the element(s) will gradually fade in or out.

Examples

Overview

```
$(element).hide()           // sets display: none
$(element).show()           // sets display to original value
$(element).toggle()         // toggles between the two
$(element).is(':visible')    // returns true or false
$('element:visible')        // matches all elements that are visible
$('element:hidden')         // matches all elements that are hidden

$('element').fadeIn();       // display the element
$('element').fadeOut();      // hide the element

$('element').fadeIn(1000);    // display the element using timer
$('element').fadeOut(1000);   // hide the element using timer

// display the element using timer and a callback function
$('element').fadeIn(1000, function(){
    // code to execute
});

// hide the element using timer and a callback function
$('element').fadeOut(1000, function(){
    // code to execute
});
```

Toggle possibilities

Simple `toggle()` case

```
function toggleBasic() {
    $(".target1").toggle();
}
```

With specific *duration*

```
function toggleDuration() {
    $(".target2").toggle("slow"); // A millisecond duration value is also acceptable
}
```

...and *callback*

```
function toggleCallback() {
    $(".target3").toggle("slow",function(){alert('now do something');});
}
```

...or with *easing* and *callback*.

```
function toggleEasingAndCallback() {
    // You may use jQueryUI as the core only supports linear and swing easings
    $(".target4").toggle("slow","linear",function(){alert('now do something');});
}
```

...or with a variety of *options*.

```
function toggleWithOptions() {
    $(".target5").toggle(
        { // See all possible options in: api.jquery.com/toggle/#toggle-options
          duration:1000, // milliseconds
          easing:"linear",
          done:function(){
              alert('now do something');
          }
        }
    );
}
```

It's also possible to use a *slide* as animation with `slideToggle()`

```
function toggleSlide() {
    $(".target6").slideToggle(); // Animates from top to bottom, instead of top corner
}
```

...or fade in/out by changing opacity with `fadeToggle()`

```
function toggleFading() {
    $( ".target7" ).fadeToggle("slow")
}
```

...or toggle a class with `toggleClass()`

```
function toggleClass() {
    $(".target8").toggleClass('active');
}
```

A common case is to use `toggle()` in order to show one element while hiding the other (same class)

```
function toggleX() {
    $(".targetX").toggle("slow");
}
```

All the above examples can be found [here](#)

Read Element Visibility online: <https://riptutorial.com/jquery/topic/1298/element-visibility>

Chapter 12: Events

Remarks

jQuery internally handles events via the [addEventListener](#) function. This means it is perfectly legal to have more than one function bound to the same event for the same DOM element.

Examples

Attach and Detach Event Handlers

Attach an Event Handler

Since version [1.7](#) jQuery has the event API `.on()`. This way any [standard javascript event](#) or custom event can be bound on the currently selected jQuery element. There are shortcuts such as `.click()`, but `.on()` gives you more options.

HTML

```
<button id="foo">bar</button>
```

jQuery

```
$( "#foo" ).on( "click", function() {  
    console.log( $( this ).text() ); //bar  
});
```

Detach an Event Handler

Naturally you have the possibility to detach events from your jQuery objects too. You do so by using `.off( events [, selector ] [, handler ] )`.

HTML

```
<button id="hello">hello</button>
```

jQuery

```
$('#hello').on('click', function(){
    console.log('hello world!');
    $(this).off();
});
```

When clicking the button `$(this)` will refer to the current jQuery object and will remove all attached event handlers from it. You can also specify which event handler should be removed.

jQuery

```
$('#hello').on('click', function(){
    console.log('hello world!');
    $(this).off('click');
});

$('#hello').on('mouseenter', function(){
    console.log('you are about to click');
});
```

In this case the `mouseenter` event will still function after clicking.

Delegated Events

Let's start with example. Here is a very simple example HTML.

Example HTML

```
<html>
  <head>
  </head>
  <body>
    <ul>
      <li>
        <a href="some_url/">Link 1</a>
      </li>
      <li>
        <a href="some_url/">Link 2</a>
      </li>
      <li>
        <a href="some_url/">Link 3</a>
      </li>
    </ul>
  </body>
</html>
```

The problem

Now in this example, we want to add an event listener to all `<a>` elements. The problem is that the list in this example is dynamic. `<li>` elements are added and removed as time passes by.

However, the page does not refresh between changes, which would allow us to use simple click event listeners to the link objects (i.e. `$('#a').click()`).

The problem we have is how to add events to the `<a>` elements that come and go.

Background information - Event propagation

Delegated events are only possible because of event propagation (often called event bubbling). Any time an event is fired, it will bubble all the way up (to the document root). They *delegate* the handling of an event to a non-changing ancestor element, hence the name "delegated" events.

So in example above, clicking `<a>` element link will trigger 'click' event in these elements in this order:

- a
- li
- ul
- body
- html
- document root

Solution

Knowing what event bubbling does, we can catch one of the wanted events which are propagating up through our HTML.

A good place for catching it in this example is the `<ul>` element, as that element does is not dynamic:

```
$('#ul').on('click', 'a', function () {
    console.log(this.href); // jQuery binds the event function to the targeted DOM element
                             // this way `this` refers to the anchor and not to the list
    // Whatever you want to do when link is clicked
});
```

In above:

- We have 'ul' which is the recipient of this event listener
- The first parameter ('click') defines which events we are trying to detect.
- The second parameter ('a') is used to declare where the event needs to *originate* from (of all child elements under this event listener's recipient, ul).
- Lastly, the third parameter is the code that is run if first and second parameters' requirements are fulfilled.

In detail how solution works

1. User clicks `<a>` element
2. That triggers click event on `<a>` element.
3. The event start bubbling up towards document root.
4. The event bubbles first to the `<li>` element and then to the `<ul>` element.
5. The event listener is run as the `<ul>` element has the event listener attached.
6. The event listener first detects the triggering event. The bubbling event is 'click' and the listener has 'click', it is a pass.
7. The listener checks tries to match the second parameter ('a') to each item in the bubble chain. As the last item in the chain is an 'a' this matches the filter and this is a pass too.
8. The code in third parameter is run using the matched item as it's `this`. If the function does not include a call to `stopPropagation()`, the event will continue propagating upwards towards the root (`document`).

Note: If a suitable non-changing ancestor is not available/convenient, you should use `document`. As a habit do not use `'body'` for the following reasons:

- `body` has a bug, to do with styling, that can mean mouse events do not bubble to it. This is browser dependant and can happen when the calculated body height is 0 (e.g. when all child elements have absolute positions). Mouse events always bubble to `document`.
- `document` *always* exists to your script, so you can attach delegated handlers to `document` outside of a *DOM-ready handler* and be certain they will still work.

Document Loading Event .load()

If you want your script to wait until a certain resource was loaded, such as an image or a PDF you can use `.load()`, which is a shortcut for shortcut for `.on( "load", handler)`.

HTML

```

```

jQuery

```
$( "#image" ).load(function() {  
    // run script  
});
```

Events for repeating elements without using ID's

Problem

There is a series of repeating elements in page that you need to know which one an event occurred on to do something with that specific instance.

Solution

- Give all common elements a common class
- Apply event listener to a class. `this` inside event handler is the matching selector element the event occurred on
- Traverse to outer most repeating container for that instance by starting at `this`
- Use `find()` within that container to isolate other elements specific to that instance

HTML

```
<div class="item-wrapper" data-item_id="346">
  <div class="item"><span class="person">Fred</span></div>
  <div class="item-toolbar">
    <button class="delete">Delete</button>
  </div>
</div>
<div class="item-wrapper" data-item_id="393">
  <div class="item"><span class="person">Wilma</span></div>
  <div class="item-toolbar">
    <button class="delete">Delete</button>
  </div>
</div>
```

jQuery

```
$(function() {
  $('.delete').on('click', function() {
    // "this" is element event occurred on
    var $btn = $(this);
    // traverse to wrapper container
    var $itemWrap = $btn.closest('.item-wrapper');
    // look within wrapper to get person for this button instance
    var person = $itemWrap.find('.person').text();
    // send delete to server and remove from page on success of ajax
    $.post('url/string', { id: $itemWrap.data('item_id') }).done(function(response) {
      $itemWrap.remove()
    }).fail(function() {
      alert('Oops, not deleted at server');
    });
  });
});
```

originalEvent

Sometimes there will be properties that aren't available in jQuery event. To access the underlying properties use `Event.originalEvent`

Get Scroll Direction

```
$(document).on("wheel", function(e) {
  console.log(e.originalEvent.deltaY)
  // Returns a value between -100 and 100 depending on the direction you are scrolling
})
```

Switching specific events on and off via jQuery. (Named Listeners)

Sometimes you want to switch off all previously registered listeners.

```
//Adding a normal click handler
$(document).on("click",function(){
    console.log("Document Clicked 1")
});
//Adding another click handler
$(document).on("click",function(){
    console.log("Document Clicked 2")
});
//Removing all registered handlers.
$(document).off("click")
```

An issue with this method is that ALL listeners binded on `document` by other plugins etc would also be removed.

More often than not, we want to detach all listeners attached only by us.

To achieve this, we can bind named listeners as,

```
//Add named event listener.
$(document).on("click.mymodule",function(){
    console.log("Document Clicked 1")
});
$(document).on("click.mymodule",function(){
    console.log("Document Clicked 2")
});

//Remove named event listener.
$(document).off("click.mymodule");
```

This ensures that any other click listener is not inadvertently modified.

Read Events online: <https://riptutorial.com/jquery/topic/1321/events>

Chapter 13: Getting and setting width and height of an element

Examples

Getting and setting width and height (ignoring border)

Get width and height:

```
var width = $('#target-element').width();  
var height = $('#target-element').height();
```

Set width and height:

```
$('#target-element').width(50);  
$('#target-element').height(100);
```

Getting and setting innerWidth and innerHeight (ignoring padding and border)

Get width and height:

```
var width = $('#target-element').innerWidth();  
var height = $('#target-element').innerHeight();
```

Set width and height:

```
$('#target-element').innerWidth(50);  
$('#target-element').innerHeight(100);
```

Getting and setting outerWidth and outerHeight (including padding and border)

Get width and height (excluding margin):

```
var width = $('#target-element').outerWidth();  
var height = $('#target-element').outerHeight();
```

Get width and height (including margin):

```
var width = $('#target-element').outerWidth(true);  
var height = $('#target-element').outerHeight(true);
```

Set width and height:

```
$('#target-element').outerWidth(50);  
$('#target-element').outerHeight(100);
```

Read [Getting and setting width and height of an element](https://riptutorial.com/jquery/topic/2167/getting-and-setting-width-and-height-of-an-element) online:

<https://riptutorial.com/jquery/topic/2167/getting-and-setting-width-and-height-of-an-element>

Chapter 14: jQuery .animate() Method

Syntax

1. (selector).animate({styles},{options})

Parameters

Parameter	Details
properties	An object of CSS properties and values that the animation will move toward
duration	(default: 400) A string or number determining how long the animation will run
easing	(default: swing) A string indicating which easing function to use for the transition
complete	A function to call once the animation is complete, called once per matched element.
start	specifies a function to be executed when the animation begins.
step	specifies a function to be executed for each step in the animation.
queue	a Boolean value specifying whether or not to place the animation in the effects queue.
progress	specifies a function to be executed after each step in the animation.
done	specifies a function to be executed when the animation ends.
fail	specifies a function to be executed if the animation fails to complete.
specialEasing	a map of one or more CSS properties from the styles parameter, and their corresponding easing functions.
always	specifies a function to be executed if the animation stops without completing.

Examples

Animation with callback

Sometimes we need to change words position from one place to another or reduce size of the words and change the color of words automatically to improve the attraction of our website or web apps. JQuery helps a lot with this concept using `fadeIn()`, `hide()`, `slideDown()` but its functionality

are limited and it only done the specific task which assign to it.

Jquery fix this problem by providing an amazing and flexible method called `.animate()`. This method allows to set custom animations which is used css properties that give permission to fly over borders. for example if we give css style property as `width:200;` and current position of the DOM element is 50, animate method reduce current position value from given css value and animate that element to 150. But we don't need to bother about this part because animation engine will handle it.

```
<script src="https://ajax.googleapis.com/ajax/libs/jquery/3.1.1/jquery.min.js"></script>
<script>
    $("#btn1").click(function(){
        $("#box").animate({width: "200px"});
    });
</script>

<button id="btn1">Animate Width</button>
<div id="box" style="background:#98bf21;height:100px;width:100px;margin:6px;"></div>
```

List of css style properties that allow in `.animate()` method.

backgroundPositionX, backgroundPositionY, borderWidth, borderBottomWidth, borderLeftWidth, borderRightWidth, borderTopWidth, borderSpacing, margin, marginBottom, marginLeft, marginRight, marginTop, outlineWidth, padding, paddingBottom, paddingLeft, paddingRight, paddingTop, height, width, maxHeight, maxWidth, minHeight, minWidth, fontSize, bottom, left, right, top, letterSpacing, wordSpacing, lineHeight, textIndent,

Speed specified in `.animate()` method.

milliseconds (Ex: 100, 1000, 5000, etc.),
"slow",
"fast"

Easing specified in `.animate()` method.

"swing"

"linear"

Here is some examples with complex animation options.

Eg 1:

```
$( "#book" ).animate({
  width: [ "toggle", "swing" ],
  height: [ "toggle", "swing" ],
  opacity: "toggle"
}, 5000, "linear", function() {
    $( this ).after( "<div>Animation complete.</div>" );
});
```

Eg 2:

```
$("#box").animate({
  height: "300px",
  width: "300px"
}, {
  duration: 5000,
  easing: "linear",
  complete: function(){
    $(this).after("<p>Animation is complete!</p>");
  }
});
```

Read jQuery .animate() Method online: <https://riptutorial.com/jquery/topic/5064/jquery--animate---method>

Chapter 15: jQuery Deferred objects and Promises

Introduction

jQuery promises are a clever way of chaining together asynchronous operations in a building-block manner. This replaces old-school nesting of callbacks, which are not so easily reorganised.

Examples

Basic promise creation

Here is a very simple example of a function that "*promises* to proceed when a given time elapses". It does that by creating a new `Deferred` object, that is resolved later and returning the `Deferred`'s promise:

```
function waitPromise(milliseconds) {

    // Create a new Deferred object using the jQuery static method
    var def = $.Deferred();

    // Do some asynchronous work - in this case a simple timer
    setTimeout(function() {

        // Work completed... resolve the deferred, so it's promise will proceed
        def.resolve();
    }, milliseconds);

    // Immediately return a "promise to proceed when the wait time ends"
    return def.promise();
}
```

And use like this:

```
waitPromise(2000).then(function() {
    console.log("I have waited long enough");
});
```

Asynchronous Promises Chaining

If you have multiple asynchronous tasks that needs to occur one after the other, you will need to chain together their promise objects. Here is a simple example:

```
function First() {
    console.log("Calling Function First");
    return $.get("/ajax/GetFunction/First");
}
```

```

function Second() {
    console.log("Calling Function Second");
    return $.get("/ajax/GetFunction/Second");
}

function Third() {
    console.log("Calling Function Third");
    return $.get("/ajax/GetFunction/Third");
}

function log(results){
    console.log("Result from previous AJAX call: " + results.data);
}

First().done(log)
    .then(Second).done(log)
    .then(Third).done(log);

```

jQuery ajax() success, error VS .done(), .fail()

success and Error : A **success** callback that gets invoked upon successful completion of an Ajax request.

A **failure** callback that gets invoked in case there is any error while making the request.

Example:

```

$.ajax({
    url: 'URL',
    type: 'POST',
    data: yourData,
    datatype: 'json',
    success: function (data) { successFunction(data); },
    error: function (jqXHR, textStatus, errorThrown) { errorFunction(); }
});

```

.done() and .fail() :

.ajax().done(function(data, textStatus, jqXHR){}); Replaces method .success() which was deprecated in jQuery 1.8. This is an alternative construct for the success callback function above.

.ajax().fail(function(jqXHR, textStatus, errorThrown){}); Replaces method .error() which was deprecated in jQuery 1.8. This is an alternative construct for the complete callback function above.

Example:

```

$.ajax({
    url: 'URL',
    type: 'POST',
    data: yourData,
    datatype: 'json'
})
.done(function (data) { successFunction(data); })
.fail(function (jqXHR, textStatus, errorThrown) { errorFunction(); });

```

Get the current state of a promise

By default the state of a promise is pending when it is created. The state of a promise is changed when the deferred object which created the promise either resolves/rejects it.

```
var deferred = new $.Deferred();
var d1= deferred.promise({
    prop: "value"
});
var d2= $("div").promise();
var d3= $("div").hide(1000).promise();

console.log(d1.state()); // "pending"
console.log(d2.state()); // "resolved"
console.log(d3.state()); // "pending"
```

Read jQuery Deferred objects and Promises online:

<https://riptutorial.com/jquery/topic/8308/jquery-deferred-objects-and-promises>

Chapter 16: Plugins

Examples

Plugins - Getting Started

The jQuery API may be extended by adding to its prototype. For example, the existing API already has many functions available such as `.hide()`, `.fadeIn()`, `.hasClass()`, etc.

The jQuery prototype is exposed through `$.fn`, the source code contains the line

```
jQuery.fn = jQuery.prototype
```

Adding functions to this prototype will allow those functions to be available to be called from any constructed jQuery object (which is done implicitly with each call to jQuery, or each call to `$` if you prefer).

A constructed jQuery object will hold an internal array of elements based on the selector passed to it. For example, `$('.active')` will construct a jQuery object that holds elements with the active class, at the time of calling (as in, this is not a live set of elements).

The `this` value inside of the plugin function will refer to the constructed jQuery object. As a result, `this` is used to represent the matched set.

Basic Plugin:

```
$.fn.highlight = function() {  
    this.css({ background: "yellow" });  
};  
  
// Use example:  
$("span").highlight();
```

[jsFiddle example](#)

Chainability & Reusability

Unlike the example above, jQuery Plugins are expected to be **Chainable**.

What this means is the possibility to chain multiple Methods to a same Collection of Elements like `$(".warn").append("WARNING! ").css({color:"red"})` (see how we used the `.css()` method after the `.append()`, both methods apply on the same `.warn` Collection)

Allowing one to use the same plugin on different Collections passing different customization options plays an important role in **Customization / Reusability**

```
(function($) {
```

```
$.fn.highlight = function( custom ) {

    // Default settings
    var settings = $.extend({
        color : "",                // Default to current text color
        background : "yellow"      // Default to yellow background
    }, custom);

    return this.css({             // `return this` maintains method chainability
        color : settings.color,
        backgroundColor : settings.background
    });

};

}( jQuery );

// Use Default settings
$("span").highlight();          // you can chain other methods

// Use Custom settings
$("span").highlight({
    background: "#f00",
    color: "white"
});
```

[jsFiddle demo](#)

Freedom

The above examples are in the scope of understanding basic Plugin creation. Keep in mind to not restrict a user to a limited set of customization options.

Say for example you want to build a `.highlight()` Plugin where you can pass a desired **text** String that will be highlighted and allow maximal freedom regarding styles:

```
//...
// Default settings
var settings = $.extend({
    text : "",                // text to highlight
    class : "highlight"      // reference to CSS class
}, custom);

return this.each(function() {
    // your word highlighting logic here
});
//...
```

the user can now pass a desired **text** and have complete control over the added styles by using a custom CSS class:

```
$("#content").highlight({
    text : "hello",
    class : "makeYellowBig"
});
```

jQuery.fn.extend() method

This method extends the jQuery prototype (\$.fn) object to provide new custom methods that can be chained to the jQuery() function.

For example:

```
<div>Hello</div>
<div>World!</div>

<script>
jQuery.fn.extend({
  // returns combination of div texts as a result
  getMessage: function() {
    var result;
    // this keyword corresponds result array of jquery selection
    this.each(function() {
      // $(this) corresponds each div element in this loop
      result = result + " " + $(this).val();
    });
    return result;
  }
});

// newly created .getMessage() method
var message = $("div").getMessage();

// message = Hello World!
console.log(message);
</script>
```

Read Plugins online: <https://riptutorial.com/jquery/topic/1805/plugins>

Chapter 17: Prepend

Examples

Prepending an element to a container

Solution 1:

```
$('#parent').prepend($('#child'));
```

Solution 2:

```
$('#child').prependTo($('#parent'));
```

Both solutions are prepending the element `#child` (adding at the beginning) to the element `#parent`.

Before:

```
<div id="parent">
  <span>other content</span>
</div>
<div id="child">

</div>
```

After:

```
<div id="parent">
  <div id="child">

  </div>
  <span>other content</span>
</div>
```

Prepend method

`prepend()` - Insert content, specified by the parameter, to the beginning of each element in the set of matched elements.

1. `prepend( content [, content ] )`

```
// with html string
jQuery('#parent').prepend('<span>child</span>');
// or you can use jQuery object
jQuery('#parent').prepend($('#child'));
// or you can use comma separated multiple elements to prepend
jQuery('#parent').prepend($('#child1'), $('#child2'));
```

2. `prepend(function)`

jQuery *version: 1.4* onwards you can use callback function as the argument. Where you can get arguments as index position of the element in the set and the old HTML value of the element. Within the function, `this` refers to the current element in the set.

```
jQuery('#parent').prepend(function(i,oldHTML){  
    // return the value to be prepend  
    return '<span>child</span>';  
});
```

Read Prepend online: <https://riptutorial.com/jquery/topic/1909/prepend>

Chapter 18: Selectors

Introduction

A jQuery selectors selects or finds a DOM (document object model) element in an HTML document. It is used to select HTML elements based on id, name, types, attributes, class and etc. It is based on existing CSS selectors.

Syntax

- Tag: No marker, use the tag directly
- Id: `#id`
- Class: `.className`
- Attribute: `[attributeName]`
- Attribute with value: `[attributeName = 'value']`
- Attribute starts with value `^=: [attributeName ^= 'value']`
- Attribute ends with value `$=: [attributeName $= 'value']`
- Attribute contains value `*=: [attributeName *= 'value']`
- Pseudo-selector: `:pseudo-selector`
- Any descendant: Space between selectors
- Direct children: `>` between selectors
- Adjacent sibling following the first: `+`
- Non-adjacent sibling following the first: `~`
- Or: `,` (comma) between selector

Remarks

When writing selectors for class or id or attribute which contains some special characters like

`! " # $ % & ' ( ) * + , . / : ; < = > ? @ [ \ ] ^ { | } ~`

the characters need to be escaped using two backslashes `\\`.

eg.

```
<span id="temp.foo\bar"></span>
```

the selectors will be framed like,

```
$('#temp\\ .foo\bar')
```

Examples

Types of Selectors

In jQuery you can select elements in a page using many various properties of the element, including:

- Type
- Class
- ID
- Possession of Attribute
- Attribute Value
- Indexed Selector
- [Pseudo-state](#)

If you know [CSS selectors](#) you will notice selectors in jQuery are the same (with minor exceptions).

Take the following HTML for example:

```
<a href="index.html"></a>           <!-- 1 -->
<a id="second-link"></a>             <!-- 2 -->
<a class="example"></a>              <!-- 3 -->
<a class="example" href="about.html"></a> <!-- 4 -->
<span class="example"></span>        <!-- 5 -->
```

Selecting by Type:

The following jQuery selector will select all `<a>` elements, including 1, 2, 3 and 4.

```
$("a")
```

Selecting by Class

The following jQuery selector will select all elements of class `example` (including non-a elements), which are 3, 4 and 5.

```
$(".example")
```

Selecting by ID

The following jQuery selector will select the element with the given ID, which is 2.

```
$("#second-link")
```

Selecting by Possession of Attribute

The following jQuery selector will select all elements with a defined `href` attribute, including 1 and 4.

```
$("[href]")
```

Selecting by Attribute Value

The following jQuery selector will select all elements where the `href` attribute exists with a value of `index.html`, which is just 1.

```
$("#[href='index.html']")
```

Selecting by Indexed Position (*Indexed Selector*)

The following jQuery selector will select only 1, the second `<a>` ie. the `second-link` because index supplied is 1 like `eq(1)` (Note that the index starts at 0 hence the second got selected here!).

```
$("#a:eq(1)")
```

Selecting with Indexed Exclusion

To exclude an element by using its index `:not(:eq())`

The following selects `<a>` elements, except that with the class `example`, which is 1

```
$("#a").not(":eq(0)")
```

Selecting with Exclusion

To exclude an element from a selection, use `:not()`

The following selects `<a>` elements, except those with the class `example`, which are 1 and 2.

```
$("#a:not(.example)")
```

Selecting by Pseudo-state

You can also select in jQuery using pseudo-states, including `:first-child`, `:last-child`, `:first-of-type`, `:last-of-type`, etc.

The following jQuery selector will only select the first `<a>` element: number 1.

```
$("#a:first-of-type")
```

Combining jQuery selectors

You can also increase your specificity by combining multiple jQuery selectors; you can combine any number of them or combine all of them. You can also select multiple classes, attributes and states at the same time.

```
$("#a.class1.class2.class3#someID[attr1][attr2='something'][attr3='something']:first-of-type:first-child")
```

This would select an `<a>` element that:

- Has the following classes: `class1`, `class2`, and `class3`

- Has the following ID: `someID`
- Has the following Attribute: `attr1`
- Has the following Attributes and values: `attr2` with value `something`, `attr3` with value `something`
- Has the following states: `first-child` and `first-of-type`

You can also separate different selectors with a comma:

```
$("a, .class1, #someID")
```

This would select:

- All `<a>` elements
- All elements that have the class `class1`
- An element with the id `#someID`

Child and Sibling selection

jQuery selectors generally conform to the same conventions as CSS, which allows you to select children and siblings in the same way.

- To select a non-direct child, use a space
- To select a direct child, use a `>`
- To select an adjacent sibling following the first, use a `+`
- To select a non-adjacent sibling following the first, use a `~`

Wildcard selection

There might be cases when we want to select all elements but there is not a common property to select upon (class, attribute etc). In that case we can use the `*` selector that simply selects all the elements:

```
$('#wrapper *') // Select all elements inside #wrapper element
```

Combining selectors

Consider following DOM Structure

```
<ul class="parentUl">
  <li> Level 1
    <ul class="childUl">
      <li>Level 1-1 <span> Item - 1 </span></li>
      <li>Level 1-1 <span> Item - 2 </span></li>
    </ul>
  </li>
  <li> Level 2
    <ul class="childUl">
      <li>Level 2-1 <span> Item - 1 </span></li>
      <li>Level 2-1 <span> Item - 1 </span></li>
    </ul>
  </li>
</ul>
```

```
</li>
</ul>
```

Descendant and child selectors

Given a parent `<ul>` - `parentUl` find its descendants (`<li>`),

1. Simple `$('.parent child')`

```
>> $('ul.parentUl li')
```

This gets all matching descendants of the specified ancestor *all levels down*.

2. `>` - `$('.parent > child')`

```
>> $('ul.parentUl > li')
```

This finds all matching children (*only 1st level down*).

3. Context based selector - `$('.child', 'parent')`

```
>> $('li', 'ul.parentUl')
```

This works same as 1. above.

4. `find()` - `$('.parent').find('child')`

```
>> $('ul.parentUl').find('li')
```

This works same as 1. above.

5. `children()` - `$('.parent').find('child')`

```
>> $('ul.parentUl').children('li')
```

This works same as 2. above.

Other combinators

Group Selector : `","`

Select all `<ul>` elements AND all `<li>` elements AND all `<span>` elements :

```
$('.ul, li, span')
```

Multiples selector : `""` (no character)

Select all `<ul>` elements with class `parentUl` :

```
$('.ul.parentUl')
```

Adjacent Sibling Selector : "+"

Select all `<li>` elements that are placed immediately after another `<li>` element:

```
$('.li + li')
```

General Sibling Selector : "~"

Select all `<li>` elements that are siblings of other `<li>` elements:

```
$('.li ~ li')
```

Overview

Elements can be selected by jQuery using [jQuery Selectors](#). The function returns either an element or a list of elements.

Basic selectors

```
$("#*")           // All elements
$("div")          // All <div> elements
$(".blue")        // All elements with class=blue
$(".blue.red")    // All elements with class=blue AND class=red
$(".blue, .red")  // All elements with class=blue OR class=red
$("#headline")    // The (first) element with id=headline
$("[href]")       // All elements with an href attribute
$("[href='example.com']") // All elements with href=example.com
```

Relational operators

```
$("#div span")    // All <span>s that are descendants of a <div>
$("#div > span")  // All <span>s that are a direct child of a <div>
$("#a ~ span")    // All <span>s that are siblings following an <a>
$("#a + span")    // All <span>s that are immediately after an <a>
```

Caching Selectors

Each time you use a selector in jQuery the DOM is searched for elements that match your query. Doing this too often or repeatedly will decrease performance. If you refer to a specific selector more than once you should add it to the cache by assigning it to a variable:

```
var nav = $('#navigation');
nav.show();
```

This would replace:

```
$('#navigation').show();
```

Caching this selector could prove helpful if your website needs to show/hide this element often. If there are multiple elements with the same selector the variable will become an array of these elements:

```
<div class="parent">
  <div class="child">Child 1</div>
  <div class="child">Child 2</div>
</div>

<script>
  var children = $('.child');
  var firstChildText = children[0].text();
  console.log(firstChildText);

  // output: "Child 1"
</script>
```

NOTE: The element has to exist in the DOM at the time of its assignment to a variable. If there is no element in the DOM with a class called `child` you will be storing an empty array in that variable.

```
<div class="parent"></div>

<script>
  var parent = $('.parent');
  var children = $('.child');
  console.log(children);

  // output: []

  parent.append('<div class="child">Child 1</div>');
  children = $('.child');
  console.log(children[0].text());

  // output: "Child 1"
</script>
```

Remember to reassign the selector to the variable after adding/removing elements in the DOM with that selector.

Note: When caching selectors, many developers will start the variable name with a `$` to denote that the variable is a jQuery object like so:

```
var $nav = $('#navigation');
$nav.show();
```

DOM Elements as selectors

jQuery accepts a wide variety of parameters, and one of them is an actual DOM element. Passing a DOM element to jQuery will cause the underlying array-like structure of the [jQuery object](#) to hold

that element.

jQuery will detect that the argument is a DOM element by inspecting its `nodeType`.

The most common use of a DOM element is in callbacks, where the current element is passed to the jQuery constructor in order to gain access to the jQuery API.

Such as in the `each` callback (note: `each` is an iterator function).

```
$(".elements").each(function(){
    //the current element is bound to `this` internally by jQuery when using each
    var currentElement = this;

    //at this point, currentElement (or this) has access to the Native API

    //construct a jQuery object with the currentElement(this)
    var $currentElement = $(this);

    //now $currentElement has access to the jQuery API
});
```

HTML strings as selectors

jQuery accepts a wide variety of parameters as "selectors", and one of them is an HTML string. Passing an HTML string to jQuery will cause the underlying array-like structure of the [jQuery object](#) to hold the resulting constructed HTML.

jQuery uses regex to determine if the string being passed to the constructor is an HTML string, and also that it *must* start with `<`. That regex is defined as `rquickExpr = /^(?:\s*(<[\w\W]+>)[^>]*|#[\w-]*)$/` ([explanation at regex101.com](#)).

The most common use of an HTML string as a selector is when sets of DOM elements need to be created in code only, often this is used by libraries for things like Modal popouts.

For example, a function which returned an anchor tag wrapped in a div as a template

```
function template(href,text){
    return $("<div><a href='" + href + "'>"+ text + "</a></div>");
}
```

Would return a jQuery object holding

```
<div>
  <a href="google.com">Google</a>
</div>
```

if called as `template("google.com", "Google")`.
